

Mode Identification from Multicolour Photometry and Line-Profile Variations

## 1. Introduction \& History

Goal of MI : essential for successful application of asteroseismology $\underline{\text { Prior knowledge : frequency spectrum }}$

- Up to mid-1970s: MI based on frequencies derived from photometry
- Mid-1980s: MI based on amplitude ratios from multicolour photometry
- 1971: Osaki presents a theoretical description of the calculation of LPVs :

$$
\begin{gathered}
\text { mode } \Rightarrow \text { velocity field } \Rightarrow \text { LPVs } \\
\text { LPVs } \stackrel{?}{\Rightarrow} \text { velocity field } \stackrel{?}{\Rightarrow} \text { NRP mode : identification of }(\ell, m) ?
\end{gathered}
$$

- Since mid-1980s: LPVs can be measured $\rightarrow$ Osaki's code can be applied $\Downarrow$

MI based on line-profile fitting

- End-1980s: new objective methods to perform MI are developed

## 2. Identification from Multicolour Photometry

Phase diagram of the Geneva data for the seven filters of the star HD 71913 for the frequency $4.8596 \mathrm{c} / \mathrm{d}$ : amplitude is $\neq$ for $\neq \lambda$

Variation as function of wavelength:

Due to shape of Black Body Radiation: pulsation amplitude will always be larger in blue than in red

Determine the monochromatic amount of energy radiated by the star as measured by a distant observer: $E(\lambda, t)=A(\lambda) \exp (-i \omega t)$, where the equilibrium value is defined as

$$
E(\lambda)=\frac{R^{2}}{2 \pi d^{2}} \int_{0}^{1} \int_{0}^{2 \pi} F_{\lambda}^{+} h_{\lambda}\left(\mu^{\prime}\right) \mu^{\prime} \mathrm{d} \mu^{\prime} \mathrm{d} \phi^{\prime}
$$

## Linear approximation for the perturbed quantities:

$$
F_{\lambda, 0}^{+}+\delta F_{\lambda}^{+}(\theta, \phi, t)=F_{\lambda}^{+}\left[T_{\mathrm{eff}, 0}+\delta T_{\mathrm{eff}}(\theta, \phi, t), g_{0}+\delta g_{\mathrm{e}}(\theta, \phi, t)\right]
$$

In the linear approximation, we have:

$$
\begin{align*}
\frac{\delta F_{\lambda}^{+}}{F_{\lambda, 0}^{+}} & =\left(\frac{\partial \ln F_{\lambda}^{+}}{\partial \ln T_{\mathrm{eff}}}\right) \frac{\delta T_{\mathrm{eff}}}{T_{\mathrm{eff}, 0}}+\left(\frac{\partial \ln F_{\lambda}^{+}}{\partial \ln g_{\mathrm{e}}}\right) \frac{\delta g_{\mathrm{e}}}{g_{0}}  \tag{1}\\
& \equiv \alpha_{T, \lambda} \frac{\delta T_{\mathrm{eff}}}{T_{\mathrm{eff}, 0}}+\alpha_{g, \lambda} \frac{\delta g_{\mathrm{e}}}{g_{0}}
\end{align*}
$$

## Examples of observed amplitude ratios:

Amplitude ratios depend on the kind of mode, but more importantly also on the effective temperature of the star (strong flux dependence!)

Final result of long theoretical computation:

$$
\begin{align*}
\delta m_{\lambda} & =-\frac{2.5}{\ln 10} \sqrt{4 \pi} \frac{\xi_{r}(R)}{R} P_{l}^{m}(\cos i) b_{l, \lambda}[-(l-1)(l-2) \cos (\omega t)  \tag{2}\\
& \left.+f_{T} \cos \left(\psi_{T}+\omega t\right)\left(\alpha_{T, \lambda}+\beta_{T, \lambda}\right)-f_{g} \cos (\omega t)\left(\alpha_{g, \lambda}+\beta_{g, \lambda}\right)\right]
\end{align*}
$$

with

$$
b_{l, \lambda}=\int_{0}^{1} \mu^{\prime} h_{\lambda}\left(\mu^{\prime}\right) P_{l} \mathrm{~d} \mu^{\prime}, \beta_{T, \lambda}=\frac{\partial \ln b_{l, \lambda}}{\partial \ln T_{\text {eff }}}, \beta_{g, \lambda}=\frac{\partial \ln b_{l, \lambda}}{\partial \ln g}
$$

See Cugier \& Daszyńska (2001), Dupret (2002), Townsend (2002), Dupret et al. (2003), Daszyńska-Daszkiewicz et al. (2003), and Randall et al. (2005).

Geometrical cancellation due to $P_{l}^{m}(\cos i)$ :

## Inclination Angles of Complete Cancellation:

| ( $l, m$ ) | IACC |  |  |  |  |  | IALC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $(1,0)$ |  |  |  |  |  | $90^{\circ}$ | $0^{\circ}$ |
| $(2,0)$ |  |  | $54.7^{\circ}$ |  |  |  | $0^{\circ}$ |
| $(3,0)$ |  | $39.2{ }^{\circ}$ |  |  |  | $90^{\circ}$ | $0^{\circ}$ |

| $(5,3)$ | $0^{\circ}$ |  |  |  | $70.5^{\circ}$ |  | $46.9^{\circ}$ |
| $(5,4)$ | $0^{\circ}$ |  |  |  |  | $90^{\circ}$ | $63.4^{\circ}$ |

Partial cancellation due to $b_{l, \lambda}$ :

$b_{l, \lambda}$ for different $l$. Lower 3 curves: $T_{\text {eff }}=6000 \mathrm{~K}, \log g=4.0$ at U (full), B (dotted) and V (dashed-dot); 2 upper curves: $T_{\text {eff }}=25000 \mathrm{~K}$, $\log g=4.0$ at $U$ and B (indistinguishable, dashed) and V (dashed-dot-dot-dot).

Observations: magnitudes for particular filters $j$ with transmission curves $w_{j}(\lambda)$ and a wavelength range from $\lambda_{j \text {, blue }}$ to $\lambda_{j \text {,red }}$ :

$$
\delta m_{j}=\frac{\int_{\lambda_{j, \text { blue }}}^{\lambda_{j, \text { red }}} \delta m_{\lambda} w_{j}(\lambda) \mathrm{d} \lambda}{\int_{\lambda_{j, \text { blue }}}^{\lambda_{j, \text { red }}} w_{j}(\lambda) \mathrm{d} \lambda}
$$

for comparisons with observations.

Eliminate the common factor

$$
-(2.5 / \ln 10) \sqrt{4 \pi}\left(\xi_{r}(R) / R\right) P_{l}^{m}(\cos i)
$$

by considering amplitude ratios for different photometric bands. We lose information on $i$ and $m \ldots$

For highest $\mathrm{S} / \mathrm{N}$, take ampl. ratios w.r.t. filter with lowest relative error.

## Early applications for $\delta$ Sct stars:

## Mode identification schemes using only amplitudes

1. Compute stellar models that cover observational error box in ( $T_{\text {eff }}, \log g$ ).
2. Perform non-adiabatic computations to derive $f_{T}, \psi_{T}, f_{g}$ for modes with frequencies close to the observed ones, for different degree $l$, for all the models that pass through the observational error box. ( $l=0, \ldots, 4$ )
3. For each filter $j$ and for each degree $l$, compute the theoretical amplitude while omitting common factor:

$$
A_{j, \text { th }}=\frac{\int_{\lambda_{\text {blue }}}^{\lambda_{\text {red }}}\left|b_{l, \lambda}\right|\left|T_{1}+T_{2}+T_{3}\right| w_{j}(\lambda) \mathrm{d} \lambda}{\int_{\lambda_{\text {blue }}}^{\lambda_{\text {red }}} w_{j}(\lambda) \mathrm{d} \lambda}
$$

with

$$
\begin{aligned}
& T_{1} \equiv(1-l)(l+2) \\
& T_{2} \equiv f_{T} \exp \left(-\mathrm{i} \psi_{T}\right)\left(\alpha_{T, \lambda}+\beta_{T, \lambda}\right) \\
& T_{3} \equiv-f_{g}\left(\alpha_{g, \lambda}+\beta_{g, \lambda}\right)
\end{aligned}
$$

4. Choose reference filter $A_{\text {ref, th }}$ to compute the amplitude ratios.
5. Compare theoretical $A_{j, \text { th }} / A_{\text {ref,th }}$ with observed $A_{j, \text { obs }} / A_{\text {ref }, \text { obs }}$, for all stellar models through error box in $\left(T_{\text {eff }}, \log g\right)$ by visual inspection or

$$
\chi^{2}(l)=\sum_{j=1}^{\# \text { filters }}\left(\frac{A_{j, \mathrm{th}} / A_{\mathrm{ref}, \mathrm{th}}-A_{j, \mathrm{obs}} / A_{\mathrm{ref}, \mathrm{obs}}}{\sigma_{j, \mathrm{obs}}}\right)^{2}
$$

where $\sigma_{j, \text { obs }}=$ s.e. of observed amplitude ratio for filter $j$ and the reference filter.

## Example of HD 71913 = star with SpT B

| filter | amplitude | ratio | v.r. |
| :---: | :---: | :---: | :---: |
| U | 0.035 | 1.00 | $82 \%$ |
| $\mathrm{~B}_{1}$ | 0.020 | 0.57 | $70 \%$ |
| B | 0.019 | 0.54 | $72 \%$ |
| $\mathrm{~B}_{2}$ | 0.018 | 0.51 | $66 \%$ |
| $\mathrm{~V}_{1}$ | 0.017 | 0.49 | $67 \%$ |
| V | 0.016 | 0.46 | $70 \%$ |
| G | 0.015 | 0.43 | $63 \%$ |

Amplitude ratios as a function of $\lambda$ for the 4 best solutions of HD 71913. Full line: $\ell=0$, dashed: $\ell=1$, dotted: $\ell=3$, dot-dashed: $\ell=2$.

Application to $\beta$ Cep star $\nu$ Eri (Handler et al. 2004):

Application to $\beta$ Cep star $\nu$ Eri (De Ridder et al. 2004):

| ID | Frequency <br> $\left(\mathrm{d}^{-1}\right)$ | Amplitude <br> $\left(\mathrm{km} \mathrm{s}^{-1}\right)$ | Amplitude <br> $(\mathrm{mmag})$ | Degree <br> $l$ |
| :---: | :---: | :---: | :---: | :---: |
